

PATENT

ORAL DELIVERY OF ADENO-ASSOCIATED VIRAL VECTORS

ACKNOWLEDGEMENTS

This invention was supported in part by NIH grants NS28227 and NS06208. The U.S. Government has rights in this invention as a result of this support.

INTRODUCTIONTechnical Field

This invention is in the field of gene expression and is particularly directed to expression of gene products in the gut of an animal.

Background

Adeno-associated virus (AAV) vectors have been proposed and patented as vectors for expressing gene products in animals. See, for example, U.S. patent No. 5,193,941, issued 18 August 1992, WO 9413788, as well as U.S. serial Nos. 08/227,319, the last application arising from the laboratory of the present inventor. A number of patents and other publications describe numerous AAV vectors and their uses, the uses generally being related to expression of gene products either in vitro (usually tissue cultures) or in vivo (usually in the lungs or oral mucosa, the normal sites of AAV infection, although U.S. application serial No. 08/227,319 relates to expression in the central nervous system).

Investigations in the laboratory of the present inventor have surprisingly discovered that AAV vectors can act as effective, long-term expression systems in the gut of animals after oral ingestion. This discovery provides a new method of expressing desirable gene products and control elements in the gut of animals, including humans.

SUMMARY OF THE INVENTION

Accordingly, it is an object of the invention to provide new uses for AAV vectors that have already been developed for other purposes.

1 It is a further object of the invention to provide new recombinant AAV
2 vectors containing gut-directed gene expression systems.

3 These and other objects of the invention have been accomplished by
4 providing a method of expressing a gene product in the gut of an animal, which
5 comprises administering a recombinant AAV vector to the gut of the animal, wherein the
6 vector comprises a non-AAV gene of interest ligated into an AAV vector.

8 BRIEF DESCRIPTION OF THE DRAWINGS

9 The invention will be better understood by reference to the following detailed
10 description of the invention when considered in combination with the drawings that form
11 part of the specification, wherein:

12 Figure 1 is a graph showing plasma glucose and animal weight following an
13 acute lactose challenge and a lactose-only diet. A. The change in plasma glucose
14 following the ingestion of lactose in overnight fasted rats. Rats were studied 1 week
15 following AAVlac or PBS administration. B. The oral lactose challenge was repeated
16 after 14 days on the lactose diet. C. The weights of rats at baseline, 1 week and 2 weeks
17 following a 14 day lactose and water diet. The diet commenced 1 week following oral
18 AAVlac or PBS treatment.

19 Figure 2. A. The change in plasma glucose following the ingestion of
20 lactose in overnight fasted rats, which were challenged 120 days following a single
21 peroral dose of AAVlac or PBS. B. The weights of rats at baseline, 1 week and
22 2 weeks following a 14 day lactose and water diet. The diet commenced 120 days
23 following oral AAVlac or PBS treatment.

25 DESCRIPTION OF SPECIFIC EMBODIMENTS

26 The present invention is quite straightforward: prior to this invention
27 recombinant AAV vectors were well known and were known to be able to transduce a
28 number of cells and tissues, but had not been used or suggested for use in expressing
29 gene products in the gut of animals. The invention therefore comprises administering to
30 the gut of a target animal a recombinant AAV vector containing a gene whose expression
31 is desired (along with the appropriate control elements, if desired or necessary in the
32 normal manner for vectors). No new vectors are required, as previously known AAV

1 vectors have been shown to work well for gut expression. Thus the invention is in part a
2 discovery that no particular adaption of AAV vectors is required for gut expression,
3 which is surprising in view of the strict requirements for AAV reproduction (i.e.,
4 presence of a helper virus) and the normal association of AAV with the lungs and nasal
5 passages.

6 A number of scientific and patent publications describe the state of the art in
7 the AAV vector field. Since no particular adaptations of prior art vectors are required for
8 practice of the present invention, there is no need here to detail at great length the already
9 well-known state of the art. However, the following publications are herein incorporated
10 by reference, as are the patent and the patent applications (and their published
11 equivalents) identified in the Introduction section of this specification, as these materials

30
31 Actual delivery of the viral vector for purposes of the invention is
32 accomplished by using any physical method that will transport the AAV recombinant

0042700 0955327 042700

1 vector to the gut. In this discussion on administration, "AAV vector" means both a bare
2 recombinant AAV DNA vector or AAV vector DNA packaged into viral capsids. Simply
3 dissolving an AAV vector in phosphate buffered saline has been demonstrated to be
4 sufficient for useful gut expression, and there are no known restrictions on the carriers or
5 other components that can be coadministered with the vector (although compositions that
6 degrade DNA should be avoided in the normal manner with vectors). Pharmaceutical
7 compositions can be prepared as oral tablets, capsules, or ingestible liquids or as
8 suppositories. The vectors can be used with any pharmaceutically acceptable carrier for
9 ease of administration and handling.

10 The AAV vector may be orally administered, for example, with an inert
11 diluent or with an assimilable edible carrier, or it may be enclosed in hard or soft shell
12 gelatin capsules, or it may be compressed into tablets, or it may be incorporated directly
13 with the food of the diet. For oral therapeutic administration, the AAV vector may be
14 incorporated with excipient and used in the form of ingestible tablets, buccal tablets,
15 troches, capsules, elixirs, suspensions, syrups, wafers, and the like. Such compositions
16 and preparations should contain at least 1 μg , preferably 10-1000 μg of AAV vector
17 DNA, or 5×10^3 to 5×10^6 infectious units AAV vector per kg body weight. The
18 amount of AAV vector in a therapeutically useful composition is that which is sufficient
19 to produce gene expression at a therapeutically useful level. Preferred compositions or
20 preparations according to the present invention are prepared so that an oral dosage unit
21 form contains between about 10 and 1000 μg of AAV vector DNA or 10^4 to 10^6
22 infectious units AAV vector.

23 The tablets, troches, pills, capsules and the like may also contain the
24 following: a binder such as polyvinylpyrrolidone, gum tragacanth, acacia, sucrose, corn
25 starch or gelatin; an excipient such as calcium phosphate, sodium citrate and calcium
26 carbonate; a disintegrating agent such as corn starch, potato starch, tapioca starch, certain
27 complex silicates, alginic acid and the like; a lubricant such as sodium lauryl sulfate, talc
28 and magnesium stearate; a sweetening agent such as sucrose, lactose or saccharin; or a
29 flavoring agent such as peppermint, oil of wintergreen or cherry flavoring. Solid
30 compositions of a similar type are also employed as fillers in soft and hard-filled gelatin
31 capsules; preferred materials in this connection also include lactose or milk sugar as well
32 as high molecular weight polyethylene glycols. When the dosage unit form is a capsule,

1 it may contain, in addition to materials of the above type, a liquid carrier. Various other
2 materials may be present as coatings or to otherwise modify the physical form of the
3 dosage unit. For instance, tablets, pills, or capsules may be coated with shellac, sugar or
4 both. A syrup or elixir may contain the AAV vector, sucrose as a sweetening agent,
5 methyl and propylparabens as preservatives, a dye, flavoring such as cherry or orange
6 flavor, emulsifying agents and/or suspending agents, as well as such diluents as water,
7 ethanol, propylene glycol, glycerin and various like combinations thereof. Of course, any
8 material used in preparing any dosage unit form should be pharmaceutically pure and
9 substantially non-toxic in the amounts employed. In addition, the AAV vector may be
10 incorporated into sustained-release preparations and formulations.

Since AAV has in the past been shown to have a broad host range (for pulmonary expression) and has now been demonstrated to be operable in the gut, there are no known limits on the animals in which gut expression can take place, although expression in animals with evolutionarily developed small and large intestines is preferred, particularly in mammals, birds, fish, and reptiles, especially domesticated mammals and birds such as cattle, sheep, pigs, horses, dogs, cats, chickens, and turkeys. Both human and veterinary uses are particularly preferred.

The gene being expressed can be either a DNA segment encoding a protein, with whatever control elements (e.g., promoters, operators, ribosome binding sites) are desired by the user, or a non-coding DNA segment, the transcription of which produces all or part of some RNA-containing molecule or anti-sense molecule that is functional in cells. Since the present invention is directed to a route of delivery and to the vector rather than to the material being delivered, there are no limitations on the foreign DNA (non-AAV DNA) being delivered by the vector. While delivery of genes associated with correction of genetic deficiencies related to gut expression is preferred, expression of genes in the gut has the capability of correcting aberrant gene expression in other locations as a result of transport of expression products throughout the body.

We have demonstrated the invention by correcting lactose deficiency in the gut. We used a recombinant adeno-associated virus (AAV) expressing β -galactosidase (AAVlac) and delivered the vector to the proximal intestine using a peroral route. Lactase-deficient rats that received AAVlac were able to metabolize an acute lactose load as demonstrated by a rise in plasma glucose. In contrast, phosphate-buffered saline(PBS)-

002207265550
1 treated controls demonstrated no effect of lactose on plasma glucose. Furthermore, when
2 animals were placed on a restricted, lactose-only diet, PBS-treated rats continued to lose
3 weight over the entire 2-week test-diet period. In contrast, AAVlac-treated animals had
4 no weight loss during the second week. PCR and RT-PCR and histological analysis
5 confirmed intestinal persistence of viral DNA and expression of the vector-encoded β -
6 galactosidase for the life of the animal (extending to 6 months). Moreover, when animals
7 were re-challenged with a lactose load at 3 months after a single AAVlac or PBS
8 treatment, AAVlac animals retained their ability to metabolize lactose and maintained
9 body weight on a lactose diet. These data indicate that oral delivery of an AAV vector
10 can result in long-lasting phenotypic correction of lactase deficiency.

11 This demonstration system was selected both to prove the principle of the
12 invention and to demonstrate the invention in a therapeutically useful mode. Adult-type
13 hypolactasia is genetically determined by an autosomal recessive gene (Sahi et al. Lancet
14 1973 2:823-828). It is the world's most common genetic disorder, afflicting over 50% of
15 the world's population ranging from 100% in some Southeast Asian populations to less
16 than 5% in some Northern European countries (Flatz Human Genet. 1984 36:306-310).
17 Although the symptoms associated with lactose intolerance are relatively mild and readily
18 controlled by omitting lactose-containing foods, there is some debate as to the potential
19 clinical significance of the dietary restrictions which typically accompany lactose
20 intolerance. Specifically, the reduction in calcium-intake associated with complying with
21 a lactose-free diet may lead to an acceleration in the loss of bone mass in the elderly
22 (Flatz 1987 Advances in Human Genet. 16:1-77 NY Plenum Press); and in adolescents
23 and young adults, it may reduce the bone mineral mass (Mobassaleh et al. Pediatrics
24 75:160-166 1985).

25 We elected to study lactase deficiency in the rat as a model of a
26 gastrointestinal genetic disease. We were particularly interested in determining whether
27 we could obtain phenotypic correction using an orally delivered viral vector. We have
28 previously shown that AAV vectors can result in long-term transgene expression in
29 terminally differentiated cells following *in vivo* administration (Birge et al. NEJM 1967
30 276:445-448). AAV has several features which make it particularly attractive for gene
31 therapy. It is a defective, helper-dependent virus, and the wild-type is non-pathogenic.
32 Vectors can be generated which are completely free of helper virus (Bayless et al. 1975

1 NEJM 292:1156-1159). Furthermore, some recombinant AAV vectors retain just 145
2 base terminal repeats with the entire coding sequences removed. In other AAV vectors,
3 non-AAV DNA is operably linked to a vector comprising a double-D AAV genomic
4 segment consisting of 165 basepairs including an internal terminal repeat with D segments
5 at both ends. These vectors therefore are devoid of all viral genes, minimizing any
6 possibility of recombination and viral gene expression. Moreover, unlike adenovirus,
7 they do not appear to elicit any immune response. Another feature of AAV which makes
8 it potentially suitable for an orally based vector is that of hardiness - AAV is resistant to
9 temperature, pH extremes and solvents (Sandler et al. Am. J. Clin. Nutr. 1985 42:270-
10 274). Furthermore, during an active infection in humans, wild-type AAV is typically
11 found in both respiratory tract and gastrointestinal secretions, the gut is therefore a
12 normal host tissue for the virus.

13 Lactose intolerance is most commonly associated with a reduction in intestinal
14 lactase activity. Lactose digestion is dependent on the enzyme, lactase-phlorizin
15 hydrolase (LPH), a microvillar protein which has both galactosidase activity and glycosyl-
16 N-acylsphingosine glucosylhydrolase activities. However, dietary administration of yeast or
17 bacterial β -galactosidase is sufficient to confer the ability to metabolize lactose (Kaplitt
18 et al. Nature Genet. 1994 8:148-154).

19 Most mammalian species are relatively lactase deficient following weaning,
20 although this developmental change in LPH expression does not appear to be simply a
21 reduction in gene transcription. In both humans and rats, although LPH mRNA declines
22 after weaning, it reappears during adulthood. However, this increase in mRNA is not
23 associated with an increase in translation; and adult enzyme levels within the brush-border
24 remain low. It appears that some LPH protein is expressed, but the enzyme is
25 accumulated within the golgi region and is not transported to the brush-border. Based on
26 this information, we conducted the following examples to illustrate the invention. These
27 examples are not to be considered limiting of the invention unless so specified.

28 29 EXAMPLES

30 We decided to demonstrate increased enterocyte expression of β -galactosidase
31 using a viral vector and to obtain brush-border increases in enzyme activity resulting in
32 phenotypic correction in an animal model. We elected to study the adult rat as a genetic

09559327-042700

1 model of adult-onset hypolactasia. However, upon screening adult (> 4-month-old)
2 Sprague-Dawley and Fisher rats, a significant number (at least 70%) had persistent
3 lactase activity as determined by a rise in plasma glucose following an oral lactose
4 challenge test. We therefore selected only those animals that had a flat plasma glucose
5 curve following feeding with lactose.

6 Rats were randomized to receive AAVlac or vehicle. The vector (or PBS
7 vehicle) was delivered in lightly anesthetized, fasting rats using an oro-gastric tube.
8 Animals were allowed to recover and placed on a regular rat chow diet. At various times
9 following AAVlac administration, animals were challenged with lactose and plasma
10 glucose samples measured. Moreover, at one week following AAV and again at 120
11 days, animals were put on a lactose-only diet. Animal weights were monitored, and the
12 lactose challenge was repeated.

13 AAVlac DNA persistence and expression was determined using PCR and RT-
14 PCR, *in situ* RT-PCR and X-gal immunohistochemistry. No β -galactosidase (as
15 determined using X-gal staining) expression was observed within the first 3 hours.
16 However, at 6 hours, clear blue (X-gal positive) cells were seen in a characteristic
17 distribution. Moreover, this expression persisted throughout the animals' lifetime with no
18 loss of expression observed. In contrast to the endogenous enzyme activity in lactase-plus
19 animals which is at the tips of the villi and in the brush-border, the vast majority of
20 expression was within the lamina propria, even at 6 hours following peroral
21 administration. On high-power magnification, however, it appeared that some of the
22 enzyme diffused or was transported to the intestinal brush-border.

23 Administration of AAVlac did not effect the weight gain or behavior of any
24 rats fed on regular rat chow. However, on changing to the lactose-only diet, both
25 AAVlac and PBS-treated rats lost weight. Over the first week, this weight loss was
26 identical in both groups and largely reflected a reduction in food intake and a lack of
27 interest in ingesting the lactose. However, in the second week, both groups ingested the
28 lactose. Of interest, the AAVlac animals had no further weight loss; whereas, the PBS-
29 treated animals continued to lose weight at the same rate as over the first week.
30 Moreover, following a lactose challenge, the AAVlac animals had a significant elevation
31 in plasma glucose; whereas, the plasma glucose level of the PBS-treated animals remained
32 flat (Fig. 1).

1 A group of animals was followed for 4 months following a single oral
2 administration of the vector. At 120 days these rats were rechallenged with a lactose load
3 and then recommenced on a lactose-only diet. In a manner similar to the challenge
4 during the first week following AAVlac administration, the vector-treated animals
5 increased plasma glucose whereas the controls had no response. Furthermore, the PBS-
6 treated animals had persistent weight loss on the lactose diet, whereas the AAVlac-treated
7 animals were able to maintain body weight during the second week (Fig. 2).

8 9 Experimental Details

10 Adult (age > 4 months), male Fisher 344 rats were screened using an oral
11 lactose challenge. Rats were fasted overnight. On the morning of the test, a baseline,
12 fasting plasma glucose level was taken from blood obtained from the tail vein. The
13 animals were then administered 2 gr lactose and the plasma glucose was again measured
14 in a tail vein sample at 30 minutes. Plasma glucose was measured using a Beckman
15 Glucose Analyzer II as previously described (During MJ et al. J Clin Invest 1995;
16 95:2403-2408). Rats which had an increase in plasma glucose of greater than 5 mg/dl
17 were excluded from further study. Rats with flat ($\Delta < 5$ mg/dl) were randomized to 2
18 groups: A) AAVlac and B) PBS. Rats randomized to AAVlac were lightly anesthetized
19 with ketamine/xylazine (8/80 mg/kg i.p.) and an oro-gastric tube inserted. 10 microliters
20 of AAVlac (titer 5×10^6 /ml in a carrier solution or 0.5ml PBS or PBS alone was infused.
21 Rats were allowed to recover and returned to *ad libitum* access to water and rat chow.
22 AAVlac is the recombinant AAV vector prepared from pAB11 as described (Goodman
23 et al. Blood 1994 84:1492-1500).

24 Rats were fasted overnight, and blood was taken by nicking the tail vein.
25 Rats were then given a 30 minute access to 2 gram of lactose (Sigma, St. Louis) in their
26 home cages. Thirty minutes from the midpoint of the lactose meal, a second tail vein
27 sample was taken. The blood was immediately centrifuged upon collection and the
28 plasma analyzed for glucose using the Beckman glucose analyzer. In preliminary studies
29 we had determined that a forced oral dose of lactose using either an orogastric or other
30 forced feeding resulted in a highly variable stress hyperglycemic response. Moreover,
31 eating behavior *per se* was insufficient to raise plasma glucose.

Rat chow was removed from housing cages and was replaced with 100% lactose (Sigma, St. Louis). *Ad libitum* water access was continued at all times. Animals were weighed at the beginning and at 7 days and 14 days after commencement of the lactose diet. At the end of 14 days the animals, the lactose was removed and the rats were fed regular rat chow.

These studies demonstrate the feasibility of administering an AAV vector orally to obtain long-term gene expression. Moreover, there was no loss of expression evidenced over a 6-month period, and phenotypic correction extended to at least 4 months.

In normal rats, LPH expression is observed within the enterocytes with the protein transported to the brush-border. The expression of β -galactosidase in our study was somewhat atypical in that expression was most apparent in the lamina propria, with little expression in enterocytes. As turnover of enterocytes occurs every 3-5 days, it might be expected that after 4 or 5 days expression would not be seen within this population of cells. Alternatively, a few progenitor cells in the crypts may have been transduced, although we did not observe any persistent gene expression in enterocytes at both the tips of the villi or in the depths of the crypts. In contrast, as early as 6 hours following AAVlac administration, expression was observed within the lamina propria. This finding is consistent with the function of M cells within the gut. M cells are specialized gut epithelial cells which are scattered throughout the intestine but are found most concentrated overlying Peyer's patches and clusters of immune cells. M cells essentially scavenge foreign proteins, viruses and bacteria and rapidly (within 3 hours) transport these foreign agents to the immune cells within the lamina propria. The early expression of vector encoded β -galactosidase within the lamina propria is consistent with this pathway. In high powered sections we were able to see enzyme activity (as demonstrated by X-gal staining) extending down through the enterocytes to the brush border, thus contributing to the phenotypic correction we observed in this model. However, the greatest expression was within the lamina propria. The gut antigen presenting cells (APC) may be the best cells to generate systemic immune responses and are a target for vaccine development (Berns et al. Adv. Virus Res. 1979 25:407-409). Oral AAV vectors may therefore be very attractive choice for immunization. The persistent expression within the vascular lamina propria also suggest this route may be
